Type 2 diabetes (T2DM) is a rapidly growing epidemic throughout the world. This epidemic is perhaps caused by increased survival of individuals in late life combined with the fact that the risk of developing T2DM is increased in the general population. Postponing the time of diagnosis, and preventing or delaying the onset of diabetes has potentially important implications in public health. Although the severity of late-stage disease is obviously an important determinant of life expectancy, many individuals with diabetes and impaired glucose regulation are able to achieve normal gly

Logstash is a tool for analyzing logs, events, or messages. The central concept is that data and events are recorded and collected in one or more files. For example, it's often used in reverse to view the events on a file and see which records are at that point, rather than view the records to. All the files you'll upload and process may be text, image, video, audio or binary data. Each file is accessed by an "event" that is essentially a short message. The way Logstash receives and processes events is by parsing various configuration files. These files often specify the kind of document it should look for and which direction the parsing should take. Read the API Documentation to learn about the syntax and individual configuration properties. With the Config file, we describe the basic configuration of the plugin, including inputs, outputs, filters, and paths. In a filter, we can work with the data in various ways; the most common way is with filters that extract one or more values from the data. For example, we could look for all the messages that contain a number higher than a certain value, or find all messages that come from the domain helloworld.com. Typically, we describe all of the inputs and outputs in the config file and then refer to specific

inputs or outputs later using a connection type. The inputs and outputs are fully described in the documentation for the plugin. This tutorial will walk through the basic configuration of the Logstash plugin.

In this blog post, we will explore one of the most common and handy Logstash plugins: the Grok filter. The most common reason to use a filter in a Logstash configuration is to parse a large volume of messages for one or more fields in the text of the message. For example, say we wanted to know which Web service calls were made on a website, such as Facebook.com or Twitter.com. We would have a log file that includes all the calls made on the Web service and another log file that tells us which Web service was accessed (along with the date and time). After some investigation, we discover that the last log entry was at 5:30 PM EDT and it was a request for www.facebook.com. The next step is to find out who sent the request. We can do this by the ID of the user that sent the request, which is found in the 'user' field.
